

Mars Helicopter

When NASA's Mars 2020 rover lands on February 18, 2021, it will be carrying a passenger onboard: the first helicopter ever designed to fly in the thin Martian air.

The Mars Helicopter is a small, autonomous aircraft that will be carried to the surface on the Red Planet attached to the belly of the Mars 2020 rover. Its mission is experimental in nature and completely independent of the Mars 2020 science mission. In the months after landing, the helicopter will be placed on the surface to test – for the first time ever – powered flight in the thin Martian air. Its performance during these experimental test flights will help inform decisions relating to considering small helicopters for future Mars missions, where they could perform in a support role as robotic scouts, surveying terrain

from above, or as full standalone science craft carrying instrument payloads. Taking to the air would give scientists a new perspective on a region's geology and even allow them to peer into areas that are too steep or slippery to send a rover. In the distant future, they might even help astronauts explore Mars.

The project is solely a demonstration of technology; it is not designed to support the Mars 2020 mission, which is searching for signs of ancient life and collecting samples of rock and sediment in tubes for potential return to Earth by later missions.

This illustration shows the Mars Helicopter on the surface of Mars.

Key Objectives

- Prove powered flight in the thin atmosphere of Mars. The Red Planet has lower gravity (about one-third that of Earth) but its atmosphere is just 1% as thick, making it much harder to generate lift.
- Demonstrate miniaturized flying technology. That requires shrinking down onboard computers, electronics and other parts so that the helicopter is light enough to take off.
- Operate autonomously. The helicopter will use solar power to charge its batteries and rely on internal heaters to maintain operational temperatures during the cold Martian nights. After receiving commands from Earth relayed through the rover, each test flight is performed without real-time input from Mars Helicopter mission controllers.

Key Features

- Weighs 4 pounds (1.8 kg)
- Solar-powered and recharges on its own
- Wireless communication system
- Two 4-foot-long (1.2- meter-long) rotor system that spins up to 2,400 revolutions per minute
- Equipped with inertial sensors, a laser altimeter and two cameras (one color and one black-and-white)

Program Management

The Mars Helicopter Project is managed for NASA's Science Mission Directorate, Washington, D.C., by the Jet Propulsion Laboratory (JPL), a division of Caltech in Pasadena, California.

At NASA Headquarters, David Lavery is the program executive for the Mars helicopter. At JPL, MiMi Aung is the Mars Helicopter project manager and J. (Bob) Balaram is chief engineer.
